

Sensor Smoothing - Easy Problem

Written by: Joshua Beard (jbeard5@uw.edu)

You are receiving data from a sensor on the rocket, but as is often the case, the data is a little noisy. We want to smooth the data out using a moving average algorithm, where we average the last five data points collected, in the hope that this will give us closer to the real value the sensor is reading. Starter code is provided in the folder where you found this pdf.

Implement the function named "smooth" in the starter code. It gets passed the last five sensor values read, and your job is to average them and return the value. Be careful though, because at first there are not five sensor values to send, so the smooth function does not get all five. Think about benefits and drawbacks to this method. What happens if we change the size of the moving average?
